

HOMEWORK 4

Read the data

We will read dataset that is about the stores. The data contains following information.

- 1.UserID: Id of a user.
- 2.Gender: Gender of the customer.
- 3.Age: Age of customer is years
- 4.EstimatedSalary: Yearly estimated salary of the customer.
- 5.Purchased: Binary value with value 1 if the customer purchased the item, 0 otherwise.

```
In [103]... options(warn=-1)
library(ggplot2)
storeData <- read.csv('social.csv')
```

Inspect the data read

```
In [104]... head(storeData)
```

User.ID	Gender	Age	EstimatedSalary	Purchased
15624510	Male	19	19000	0
15810944	Male	35	20000	0
15668575	Female	26	43000	0
15603246	Female	27	57000	0
15804002	Male	19	76000	0
15728773	Male	27	58000	0

Spends are already reduced in given data.

```
In [105]... cat("Size of Store data",dim.data.frame(storeData))
Size of Store data 400 5
```

Aim is to train a support vector machine(SVM) that will predict whether a customer will purchase or not.

Splitting the data as training and testing data

```
In [106]... # sampling data to generate 75% training data and 25% test data
sdata <- sample(nrow(storeData), nrow(storeData)*0.75)
sampledata <- sort(sample(nrow(storeData), nrow(storeData)*0.75))
trainingData<-storeData[sampledata,]
testingData<-storeData[-sampledata,]
```

```
In [107]... cat("Training Data :: ", "Size :: ", dim.data.frame(trainingData))
head(trainingData)
cat("Testing Data :: ", "Size :: ", dim.data.frame(testingData))
head(testingData)
```

Trainig Data :: Size :: 300 5

User.ID	Gender	Age	EstimatedSalary	Purchased	
2	15810944	Male	35	20000	0
3	15668575	Female	26	43000	0
5	15804002	Male	19	76000	0
9	15600575	Male	25	33000	0
11	15570769	Female	26	80000	0
13	15746139	Male	20	86000	0

Preprocessing data for modelling

```
# converting dataframe into matrix with req
ytrain <- as.matrix(trainingData$Purchased)
# creating yr for computation assigning +1
ytrain <- matrix(apply(ytrain, 1, function
colnames(ytrain) <- c("Purchased")

Defining functions for subgradient and loss function

```
In [110]... g <- function(t){
  if (t <= 1)
    return (-1)
  else
    return (0)
}

# define tn = yn<(w,xn)
# yn is the output for nth index
# xn is the input for nth index
# x = [b w1 w2]'

tn <- function(yn, x, xn){
  t <- yn * ((xn**x))
  return (t)
}

#compute loss as terminating condition
loss <-function(x,C){
  N <- dim(xtrain)[1]
  distances <- 1 - ytrain * (xtrain**x)
  distances[distances < 0] <- 0 # equivalent to max(0, distance)
  hinge_loss <- C * (sum(distances) / N)
  # calculate cost
  cost <- 1 / 2 * t(x)**x + hinge_loss
  return (cost)
}

gradient <- function(x, C){
  deltaF <- matrix(rep(0,3), nrow = 3, ncol = 1)
  sum<- matrix(rep(0,3), nrow = 3, ncol = 1)
  for (n in seq(length(ytrain))){
    t = tn(ytrain[n],x,xtrain[n,])
    gn = g(t)
    diff <- x + (C * gn * ytrain[n] * xtrain[n,])
    sum <- sum + diff
  }
  deltaF <- sum/length(ytrain)
  return (deltaF)
}
```

Defining functions execute gradient descent for SVM, generate prediction, compute accuracy and generate confusion matrix

```
In [111]... # Run gradient descent for SVM
gradientDescent <- function(x, C, alpha,thrs,maxi){
  converged<-FALSE
  i<-1
  x1<-x
  prev_lossvalue <- 0
  while(!((converged && i <= maxi))){
    {
      deltafx <- gradient(x1,C)
      if(!is.infinite(deltafx) || is.nan(norm(deltafx,type = "2"))){
        break
      }
      x1 <- x1 - (alpha*deltafx)
      lossvalue <- loss(x1,C)
      # terminating condition based on loss function
      converged <-abs(prev_lossvalue - lossvalue) < thrs * prev_lossvalue
      prev_lossvalue <- lossvalue
      i <- i+1
    }
  }
  return (list("x1"= x1,"iteration" = i-1,"converged" = converged, "lossValue" = prev_lossvalue))
}

# generate prediction
predict <- function(data,featurecoefficients){
  result <- data**featurecoefficients
  result[result >= 0] <- -1
  result[result > 0] <- 1
  return(result)
}

# compute accuracy
accuracy <- function(predicted, actual){
  return((sum(predicted==actual)/dim(predicted)[1])*100)
}

# generate confusion matrix
generateconfusionmatrix <- function(predicted, actual){
  confusionMatrix <- matrix(rep(0,4), nrow = 2, ncol = 2)
  colnames(confusionMatrix) <- c("actual(1)","actual(-1)")
  rownames(confusionMatrix) <- c("pred(1)","pred(-1)")
  confusionMatrix
  for (i in seq(length(actual))){
    {
      if (actual[i] ==1 & predicted[i] ==1){

What happens to the confusion matrix if you use C = 100? What happens to the confusion matrix if you use C = 1? Comment on what the effect of C is on the entries of the confusion matrix. What choice of C gives you the best classification accuracy results on the test data?

I ran SVM for trade-off factors 1, 50, 75 and 100. Accuracy is best (88%) for trade-off factor C = 1 while accuracy for trade-off 50, 75 and 100 is same 87%. Also as trade-off is increased from 1, there is decrease in "TRUE POSITIVE" cases from 27 to 26 and increase in "TRUE NEGATIVE" cases from 6 to 7.

Given the observation, C = 1 gives the best accuracy.
